(57) **ABSTRACT**

The present invention relates to a method of controlling a device remotely and includes: transmitting a device selecting signal; receiving a response signal from a device to be controlled that receives the device selecting signal; identifying the device to be controlled by using the response signal; changing at least one of an angle of beam spread and direction of the device selecting signal if the identified device to be controlled is two or more in number; and generating a remote control signal by using device control information corresponding to the identified device to be controlled and transmitting the generated signal to the device to be controlled.

REMOTE CONTROL DEVICE AND METHOD**TECHNICAL FIELD**

The present invention relates to a method of remotely
controlling a plurality of electronic devices.

BACKGROUND ART

Generally, a remote control device may be provided to
remotely control an operation of an electronic product, for
example, a digital television (TV), a digital versatile disk
(DVD) player, an audio device, or an air conditioner, for user
convenience.

However, because in the related art, a remote control
device for exclusive use in each electronic product is used,
a plurality of remote control devices need to be required in
a single house. Additionally, every time an electronic prod-
uct is controlled, inconvenience of needing to find and use
a remote control device corresponding to the electronic
product may be caused.

To avoid the above inconvenience, an integrated remote
control device for controlling a plurality of electronic prod-
ucts is disclosed. A scheme of controlling a target device to
be controlled using a remote control device may be broadly
classified into an infrared ray (IR) and laser communication
scheme and a radio frequency (RF) communication scheme.

DISCLOSURE OF THE INVENTION**Technical Goals**

An aspect of the present invention provides a remote
control device and method that may easily select a specific
device from a space in which a plurality of devices are
located, and may control the specific device.

Technical Solutions

In one general aspect, there is provided a remote control
method including: transmitting a device selecting signal;
receiving a response signal from a target device that is to be
controlled and that receives the device selecting signal;
identifying the target device based on the response signal;
changing at least one of an angle of beam spread and a
direction of the device selecting signal, when a plurality of
target devices to be controlled are identified; and generating
a remote control signal based on device control information
corresponding to the identified target device, and transmit-
ting the remote control signal to the target device.

In another general aspect, there is provided a remote
control method including: transmitting a device selecting
signal, in response to at least one of a key input and a voice
recognition of a user; receiving a response signal from a
target device that is to be controlled and that receives the
device selecting signal; identifying the target device based
on the response signal; selecting one of a plurality of target
devices to be controlled by recognizing a user's voice, when
the plurality of target devices are identified; and generating
a remote control signal based on device control information
corresponding to the identified target device, and transmit-
ting the remote control signal to the target device.

Effects of the Invention

According to embodiments of the present invention, a
user may intuitively, simply select a target device to be

2

controlled, and may conveniently control the target device.
In particular, the user may accurately select the target device,
based on a signal with strong straightness, for example an
infrared ray (IR) and a laser.

Additionally, when the target device is selected, a remote
control device may be controlled through a radio frequency
(RF) communication channel and accordingly, a control
signal may not need to be transmitted by avoiding an
obstacle. Thus, it is possible for the user to conveniently
control the target device.

The remote control device may download and use device
information by accessing a device during control, if neces-
sary. Thus, a target device released after manufacturing of
the remote control device may also be controlled, and a
memory capacity of the remote control device may be
efficiently used.

In addition, selection of a plurality of target devices may
be prevented by changing a characteristic of a device select-
ing signal. Thus, it is possible for the user to accurately,
easily select a desired device.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 is a block diagram illustrating a configuration of a
remote control system according to an embodiment of the
present invention.

FIG. 2 is a block diagram illustrating an example of a
configuration of a remote control device according to an
embodiment of the present invention.

FIG. 3 is a flowchart illustrating a remote control method
according to an embodiment of the present invention.

FIG. 4 is a flowchart illustrating an operation of control-
ling a target device in the method of FIG. 3.

FIG. 5 is a block diagram illustrating another example of
a configuration of a remote control device according to an
embodiment of the present invention.

FIG. 6 is a block diagram illustrating a configuration of a
target device according to an embodiment of the present
invention.

FIG. 7 is a diagram illustrating an example of a method
of selecting one of a plurality of target devices according to
an embodiment.

FIG. 8 is a diagram illustrating a method of selecting a
specific target device by adjusting an angle of beam spread
of a device selecting signal according to an embodiment.

FIG. 9 is a diagram illustrating a method of selecting a
specific target device by adjusting a direction of a device
selecting signal according to an embodiment.

FIG. 10 is a diagram illustrating a configuration of a user
interface (UI) to select a specific target device according to
an embodiment.

FIG. 11 is a diagram illustrating an example of a method
of selecting one of a plurality of target devices according to
an embodiment.

FIGS. 12 through 15 are diagrams illustrating an example
of a method of selecting a specific target device using voice
recognition and controlling the specific target device accord-
ing to a first embodiment.

FIG. 16 is a diagram illustrating another example of a
method of selecting a specific target device using voice
recognition and controlling the specific target device.

**BEST MODE FOR CARRYING OUT THE
INVENTION**

The following detailed description is provided in order to
explain a remote control device and method according to
embodiments of the present invention by referring to the
figures.

FIG. 1 is a block diagram illustrating a configuration of a remote control system according to an embodiment of the present invention. The remote control system of FIG. 1 may include a remote control device 100, and a plurality of target devices to be controlled, for example, devices 200 through 220. In the present disclosure, a target device to be controlled may be referred to as a target device.

Referring to FIG. 1, the remote control device 100 may perform a function of transmitting a remote control signal corresponding to a control command input by a user to the target device 200 and remotely controlling the target device 200.

The remote control device 100 may be implemented as a dedicated device having only a remote control function, or may be implemented by adding a remote control function to a personal device, for example, a mobile phone, a personal digital assistant (PDA), a digital multimedia broadcasting (DMB) terminal, and the like.

Additionally, the target device 200 may include, for example, various electronic devices, for example, a television (TV), an air conditioner, a video tape recorder (VTR), a refrigerator, an electric lamp, a printer, a monitor, a personal computer (PC), and the like. The target device 200 may operate based on a control signal received from the remote control device 100.

Referring to FIG. 2, the remote control device 100 may include an input unit 110, a display unit 120, a storage unit 130, a communication unit 140, and a controller 150.

The input unit 110 may be implemented as a keypad or a touch pad including number keys, letter keys, various special keys, and the like. The input unit 110 may receive an input of various commands to control the target device 200 from a user, and may transfer the commands to the controller 150.

Additionally, the input unit 110 may include a special key (hereinafter, referred to as a "device selection key") to allow a user to determine whether a device selecting signal is to be transmitted. When a user selects the device selection key, the target device 200 may be selected as a device to be controlled, by transmitting a device selecting signal to the target device 200, instead of performing a complex menu operation.

The display unit 120 may display a control menu to control the target device 200. The control menu may include a menu item corresponding to a characteristic of a corresponding target device.

For example, when the selected target device 200 is a TV, the control menu may include menu items to control a volume, a channel, and the like. When the selected target device 200 is an air conditioner, the control menu may include menu items to control a temperature, a wind direction, an air volume, and the like.

A user may verify a control menu using the display unit 120, and may input a control command to operate the target device 200 based on a user's desire using the input unit 110.

The display unit 120 may display status information of the target device 200. The status information may refer to information associated with an operation of a corresponding target device, and may include, for example, a current set temperature of an air conditioner, a charge state of a cordless phone, or information on a compact disc (CD) that is currently being played back in an audio device. The display unit 120 may also display a variety of information associated with use of the remote control device 100.

The display unit 120 may be implemented as a flat panel display, for example, a liquid crystal display (LCD), an organic light emitting diode (OLED), a plasma display, and the like.

The storage unit 130 may perform a function of storing data and various programs required to perform an operation of the remote control device 100. For example, the storage unit 130 may store device control information downloaded from the target device 200. The storage unit 130 may be implemented as a memory unit, for example, a random access memory (RAM), a read only memory (ROM), a hard disk, a flash memory, and the like.

The device control information may include a variety of information required to control the target device 200. The device control information may include, for example, a product identification code used to identify products, control menu information used to display a control menu on a screen, a control code that is transmitted to the target device 200 based on a control command input by a user and that is used to control a corresponding device, and the like.

The device control information may be provided in advance by a manufacturer of a target device, and may be stored in advance in the storage unit 130 or may be downloaded by accessing the target device 200 if necessary.

Additionally, the device control information may be provided in a form of a virtual machine (VM) application written in C, C++, Java, mobile flash, and the like.

The communication unit 140 may wirelessly transmit and receive a variety of information to and from the target device 200. For example, based on control of the controller 150, the communication unit 140 may transmit a device selecting signal to the target device 200, and may receive a response signal corresponding to the device selecting signal.

Additionally, the communication unit 140 may transmit a remote control signal to the target device 200, based on the control of the controller 150.

The communication unit 140 may receive, from the target device 200, device control information or device status information, and may transfer the device control information or the device status information to the controller 150.

The communication unit 140 may be implemented as a communication module to transmit and receive a signal using a communication scheme with strong straightness (or directivity). For example, the communication unit 140 may be implemented as an infrared ray (IR) communication module, or a laser communication module. When a radio frequency (RF) communication scheme is used, the communication unit 140 may be implemented as a communication module employing a directional antenna.

As described above, the communication unit 140 may be implemented as a module to transmit and receive a signal using a communication scheme with strong straightness and accordingly, a user may set a signal transmission direction of the communication unit 140 to a direction towards the target device 200 the user desires to control, and may press a device selection key. Thus, a device selecting signal may be transmitted to a desired target device among the devices 200 through 220, instead of performing a complex operation.

Because an IR signal or a laser signal has strong straightness, a user may control the device selecting signal to be accurately transmitted to only a desired target device among a plurality of target devices.

The controller 150 may control an overall operation of the remote control device 100, in response to a command input by a user. When a response signal is received from the target device 200, the controller 150 may identify the target device 200 based on a product identification code included in the

5

received response signal, and may determine whether the target device **200** is registered in advance.

When the target device **200** is determined to be unregistered, the controller **150** may download device control information associated with the target device **200** from the target device **200**, may store the device control information in the storage unit **130**, and may register the target device **200**.

Additionally, the controller **150** may display a control menu on the display **110**, based on the downloaded device control information, and may allow a control command to be received from the user through the input unit **110**.

The controller **150** may control the communication unit **140** to generate a control signal corresponding to a control command input by the user and to transmit the control signal to the target device **200**. For example, when a device status information verification command is input by the user, the controller **150** may transmit a control signal to request device status information to the target device **200**, and may display the device status information provided by the target device **200** on the display unit **120** so as to provide the user with the device status information.

Hereinafter, an operation of a remote control device according to an embodiment of the present invention will be further described with reference to FIGS. **3** and **4**.

FIG. **3** is a flowchart illustrating a remote control method according to an embodiment of the present invention. The remote control method is described with reference to FIGS. **1** and **2**.

Referring to FIG. **3**, when a user sets a signal transmission direction of the communication unit **140** in the remote control device **100** to a direction towards the target device **200**, and presses a device selection key using the input unit **110**, the controller **150** may transmit a device selecting signal to the target device **200** via the communication unit **140** in operation **S310**.

For example, an IR transmitter (not shown) included in the communication unit **140** may transmit an IR signal having strong straightness with a predetermined angle of beam spread, in response to selection of the device selection key. The IR signal may include information on the remote control device **100**.

The information on the remote control device **100** may be, for example, identification information used to connect the remote control device **100** and the target device **200** that receives the IR signal, using an RF communication scheme. The RF communication scheme may include, for example, a wireless local area network (WLAN) (for example, wireless-fidelity (Wi-Fi)), Bluetooth, ZigBee, or a near field communication (NFC).

When the target device **200** receives the device selecting signal and transmits a response signal, the communication unit **140** may receive the response signal, and may transfer the response signal to the controller **150** in operation **S320**.

For example, the target device **200** may extract identification information on the remote control device **100** from an IR signal received from the remote control device **100**, and may connect an RF communication network to the remote control device **100**, based on the extracted identification information.

The target device **200** may transmit the response signal to the remote control device **100**, using the connected RF communication network.

The controller **150** in the remote control device **100** may identify the target device **200**, based on a product identification code included in the received response signal in operation **S330**.

6

The controller **150** may generate a control signal corresponding to a control command input by the user, based on device control information on the identified target device **200**, and may transmit the control signal to the target device **200** to control the target device **200** in operation **S340**.

For example, the control signal may be transmitted and received between the remote control device **100** and the target device **200** via the RF communication network connected in operation **S320**.

Hereinafter, operation **S340** of controlling the target device **200** is further described with reference to FIG. **4**. When the target device **200** is identified in operation **S330**, the controller **150** may determine whether the target device **200** is registered in advance in the remote control device **100** in operation **S341**.

When the target device **200** is determined to be registered in advance (**S341**: Y), the controller **150** may display a control menu on a screen, based on control information associated with a corresponding device stored in the storage unit **130** in operation **S343**.

When the target device **200** is determined to be unregistered (**S341**: N), the controller **150** may download device control information from the target device **200**, may store the device control information in operation **S342**, and may display a control menu on a screen, based on the stored device control information in operation **S343**.

When the user inputs a control command to control a target device on the control menu (**S345**: A), the controller **150** may generate a control signal corresponding to the control command input by the user, and may transmit the control signal to the target device **200** via the communication unit **140** in operation **S347**.

When the user inputs an end command (**S345**: B), the controller **150** may display an end screen indicating that a control operation is terminated on the display unit **120**, and may terminate a remote control operation in operation **S349**.

The remote control device **100** may transmit and receive a signal using only a communication scheme with strong straightness, as described above, however, there is no limitation thereto. The device selecting signal may be transmitted using a communication scheme with strong straightness, and a remote control signal and device control information may be transmitted and received using a communication scheme with weak straightness, for example, a nondirectional communication scheme.

FIG. **5** is a block diagram illustrating a configuration of a remote control device according to an embodiment of the present invention. The above-description of FIGS. **1** through **4** is also applicable to a configuration and an operation of a remote control device **100** of FIG. **5** and accordingly, will not be repeated here.

Referring to FIG. **5**, a communication unit **160** may wirelessly transmit and receive a variety of information to and from the target device **200**. To this end, the communication unit **160** may include a first communication module **161** and a second communication module **163**.

The first communication module **161** may be implemented as a communication module to transmit a signal using a communication scheme with strong directivity, and may transmit a device selecting signal to the target device **200** using the communication scheme with strong directivity.

For example, the first communication module **161** may be implemented as an IR communication module or a laser communication module. When an RF communication

scheme is used, the first communication module **161** may be implemented as a communication module employing a directional antenna.

The second communication module **163** may be implemented as a module to transmit and receive a signal using a communication scheme with weak straightness in comparison to the first communication module **161**. The second communication module **163** may transmit a remote control signal to the target device **200**, and may receive, from the target device **200**, a response signal, device control information or device status information. Accordingly, the second communication module **163** may be implemented as a nondirectional RF communication module.

A controller **170** may control an overall operation of the remote control device **100**. For example, when a user presses a device selection key, the controller **170** may control the first communication module **161** to transmit a device selecting signal.

Additionally, when the second communication module **163** receives a response signal from the target device **200**, the controller **170** may control the second communication module **163**, may set an RF communication channel with the target device **200**, and may determine whether the target device **200** is registered in advance.

When the target device **200** is determined to be unregistered, the controller **170** may download device control information from the target device **200** via the RF communication channel, may store the device control information in a storage unit **130**, and may register a corresponding device.

Additionally, the controller **170** may display a control menu on a display **110**, based on the downloaded device control information, may receive a control command input by the user, may generate a control signal corresponding to the control command, and may transmit the control signal to the target device **200** via the RF communication channel.

For example, when a device status information verification command is input by the user, the controller **170** may transmit a control signal to request device status information to the target device **200**, and may display the device status information provided by the target device **200** on the display unit **120**, so as to provide the user with the device status information.

The remote control device **100** may include a VM (not shown) to execute a VM application written in C, C++, Java, mobile flash, and the like. When device control information is provided in the form of a VM application, the VM may execute the VM application, may display a control menu on a screen, and may receive a control command input by a user.

The VM may be implemented by a platform, for example, a general virtual machine (GVM), an extended virtual machine (XVM), a binary runtime environment for wireless (BREW), a K virtual machine (KVM), a wireless Internet terminal open platform (WITOP), a wireless Internet platform for interoperability (WIPI), and the like.

FIG. 6 is a block diagram illustrating a configuration of a target device according to an embodiment of the present invention. A target device **200** of FIG. 6 may include a transceiver **210**, a memory unit **230**, and a central processing unit **240**. Depending on embodiments, the target device **200** may further include an LED **220**.

Referring to FIG. 6, the transceiver **210** may wirelessly transmit and receive a variety of information to and from the remote control device **100**, may receive a device selecting

signal from the remote control device **100**, and may transmit a response signal corresponding to the device selecting signal.

Additionally, the transceiver **210** may receive a remote control signal from the remote control device **100**, and may transmit device control information and device status information.

The response signal may include a device identification code and accordingly, the remote control device **100** may identify a device that transmits a response signal.

The memory unit **230** may store device control information used to control the target device **200**. In response to a request of the remote control device **100**, the memory unit **230** may receive an instruction from the central processing unit **240**, and may transfer the device control information.

The central processing unit **240** may control an overall operation of the target device **200**. When a device selecting signal is received from the remote control device **100**, the central processing unit **240** may allow the LED **220** to flicker during a predetermined period of time, and may control the transceiver **210** to transmit a response signal to the remote control device **100**.

Additionally, the central processing unit **240** may transmit device control information or device status information, in response to a request of the remote control device **100**, and may control the target device **200** to perform an operation corresponding to the control signal received from the remote control device **100**.

The LED **220** may flicker during a predetermined period of time based on control of the central processing unit **240**, to indicate whether the device selecting signal is received. Accordingly, the user may verify that the device selecting signal is accurately transmitted to a desired target device **200**.

The transceiver **210** may include a first transceiver module **211**, and a second transceiver module **213**.

The first transceiver module **211** may be implemented as an IR communication module or a laser communication module, to receive a device selecting signal using a communication scheme with strong directivity. When an RF communication scheme is used, the first transceiver module **211** may be implemented as a communication module employing a directional antenna.

The second transceiver module **213** may be implemented as an RF communication scheme to transmit and receive a signal using a communication scheme with weak straightness. The second transceiver module **213** may transmit a response signal, device control information, and device status information to the remote control device **100**, and may receive a remote control signal from the remote control device **100**.

For example, the second transceiver module **213** may broadcast the response signal using the RF communication scheme, based on control of the central processing unit **240**. When the response signal is transmitted, the second transceiver module **213** may set an RF communication channel with the remote control device **100**, and may perform two-way communication.

The second transceiver module **213** may transmit device control information, status information, and the like to the remote control device **100** via the RF communication channel, may receive various remote control signals from the remote control device **100**, and may transfer the remote control signals to the central processing unit **240**.

Hereinafter, examples of a method of selecting one of a plurality of target devices will be further described with reference to FIGS. 7 through 10.

FIG. 7 is a diagram illustrating a method of selecting one of a plurality of target devices according to an embodiment.

Referring to FIG. 7, devices **201** through **204** that are controllable by the remote control device **100** based on the operations described above with reference to FIGS. **1** through **6** may be disposed adjacent to each other in a space.

An IR transmitter **141** included in the remote control device **100** may transmit, as a device selecting signal, an IR signal with straightness based on a direction in which the remote control device **100** faces. The transmitted IR signal may have a predetermined angle of beam spread θ .

When target devices are located adjacent to each other within the angle of beam spread θ of the IR signal, at least two devices may receive the device selecting signal, based on the angle of beam spread θ .

For example, in FIG. 7, a TV **201**, an electric lamp **202**, and a desk lamp **204** may receive the device selecting signal from the remote control device **100**.

In this example, each of the TV **201**, the electric lamp **202**, and the desk lamp **204** may transmit a response signal in response to the device selecting signal. Accordingly, a plurality of devices other than the TV **201** a user desires to select, that is, the electric lamp **202** and the desk lamp **204** may be selected.

In each of the TV **201**, the electric lamp **202**, and the desk lamp **204** that receive the device selecting signal, an indicator including a light emitting element, for example, an LED may flicker during a predetermined period of time and accordingly, the user may recognize that a plurality of devices are selected.

Thus, the user may need to perform an additional operation of selecting a device that the user desires to control from among the selected devices.

When a plurality of target devices are located adjacent to each other, a specific device that the user desires to control may be easily selected by adjusting a characteristic of a device selecting signal transmitted from the remote control device **100**, for example, an angle of beam spread, a direction or a distance.

FIG. 8 is a diagram illustrating a method of selecting a specific target device by adjusting an angle of beam spread of a device selecting signal according to an embodiment.

Referring to FIG. 8, when a plurality of devices (for example, a TV **201**, an electric lamp **202**, and a desk lamp **204**) are selected by a user, as shown in FIG. 7, the remote control device **100** may adjust an angle of beam spread θ of the IR signal.

For example, when each of the TV **201**, the electric lamp **202** and the desk lamp **204** receives an IR signal from the remote control device **100**, the remote control device **100** may receive a response signal from each of the devices, and may recognize that at least two devices are selected.

In this example, the controller **150** of the remote control device **100** may control an IR transmitter **141** to reduce the angle of beam spread θ of the IR signal.

The controller **150** may request a device that receives the IR signal to transmit a response signal, while reducing the angle of beam spread θ of the IR signal at a predetermined interval and transmitting the IR signal.

The angle of beam spread θ of the IR signal may continue to decrease until a response signal is received from a single device. In FIG. 8, until only a response signal is received from the TV **201**, the angle of beam spread θ of the IR signal may decrease.

According to another embodiment of the present invention, the user may adjust the angle of beam spread θ of the IR signal.

For example, when the user sets the remote control device **100** to face the TV **201**, and presses a device selection key, and when an LED of each of the electric lamp **202** and the desk lamp **204** as well as an LED of the TV **201** flickers, the user may reduce the angle of beam spread θ of the IR signal by pressing a (−) key of the remote control device **100**.

When the user verifies flickering of only the LED of the TV **201** and releases the pressed (−) key, only the TV **201** may be selected from among the plurality of devices, and the control operation described above with reference to FIGS. **1** through **6** may be performed by the remote control device **100**.

The above-described angle of beam spread θ of the IR signal may be adjusted, by adjusting a current supplied to the IR transmitter **141** using an application installed in the remote control device **100**, or by mechanically changing an optical structure of the IR transmitter **141**.

For example, the IR transmitter **141** may include an IR generator (not shown) and a lens for IR radiation (not shown). By changing a structure of the lens may be changed, or by moving the lens, an angle of beam spread θ of an IR signal transmitted from the IR transmitter **141** may be adjusted.

When the angle of beam spread θ of the IR signal is initially set to a low value, a single device may not be selected by pressing a device selection key. Accordingly, the angle of beam spread θ may be initially set to a sufficiently high value, and may desirably be gradually reduced when a plurality of devices are selected.

Conversely, when a device is not selected by a user pressing a device selection key, the controller **150** or the user may gradually increase the angle of beam spread θ of the IR signal until a single device is selected.

FIG. 9 is a diagram illustrating a method of selecting a specific target device by adjusting a direction of a device selecting signal according to an embodiment.

Referring to FIG. 9, when a plurality of devices (for example, a TV **201**, an electric lamp **202**, and a desk lamp **204**) are selected by a user, as shown in FIG. 7, the remote control device **100** may adjust a direction Φ of the IR signal.

For example, when each of the TV **201**, the electric lamp **202** and the desk lamp **204** receives an IR signal from the remote control device **100**, the remote control device **100** may receive a response signal from each of the devices, and may recognize that at least two devices are selected.

In this example, the controller **150** of the remote control device **100** may control an IR transmitter **141** to change the direction Φ of the IR signal.

The controller **150** may request a device that receives the IR signal to transmit a response signal, while changing the direction Φ of the IR signal to a right direction at a predetermined interval and transmitting the IR signal.

The direction Φ of the IR signal may continue to be changed to the right direction or the left direction, until a response signal is received from a single device. In FIG. 9, the direction Φ of the IR signal may be changed, until only a response signal is received from the TV **201**.

According to another embodiment of the present invention, the user may adjust the direction Φ of the IR signal.

For example, when the user sets the remote control device **100** to face the TV **201**, and presses a device selection key, and when an LED in each of the electric lamp **202** and the desk lamp **204** as well as an LED of the TV **201** flickers, the user may change the direction Φ of the IR signal by pressing a (+) key or (−) key of the remote control device **100**.

When the user verifies flickering of only the LED of the TV **201** and releases the pressed (+) key or (−) key, only the

11

TV **201** may be selected from among the plurality of devices, and the control operation described above with reference to FIGS. **1** through **6** may be performed by the remote control device **100**.

The adjusting of the direction Φ of the IR signal as described above may include adjusting a direction Φ of an IR signal transmitted from the IR transmitter **141** by mechanically changing a direction in which a lens for IR radiation included in the IR transmitter **141** faces.

Conversely, when a device is not selected by a user pressing a device selection key, the controller **150** or the user may change the direction Φ of the IR signal to the right direction or the left direction, until a single device is selected.

According to another embodiment of the present invention, a specific device may be selected by adjusting a distance between the remote control device **100** and a target device.

FIG. **10** is a diagram illustrating a configuration of a user interface (UI) to select a specific target device according to an embodiment.

Referring to FIG. **10**, when a plurality of devices (for example, a TV **201**, an electric lamp **202**, and a desk lamp **204**) are selected by a user, as shown in FIG. **7**, the remote control device **100** may recognize that the devices are selected, and may provide the user with information on the selected devices, using an image, a voice, a vibration, and the like.

In this example, when a distance between the remote control device **100** and a target device decreases, only a single device may receive an IR signal and may be selected.

To induce the above decrease in the distance, the remote control device **100** may inform the user of a command to move closer to a device to be controlled, using an image or sound. The command may continue to inform the user until only a response signal is received from the TV **201**.

The remote control device **100** may transmit an IR signal and may select one of a plurality of target devices, as described above with reference to FIGS. **7** through **10**, however, there is no limitation thereto. Accordingly, various signals with straightness other than the IR signal may be used to select a target device, and the above control method may also be applicable to the various signals.

Hereinafter, examples of a method of selecting a target device from among a plurality of target devices and controlling the selected target device will be further described with reference to FIGS. **11** through **16**.

FIG. **11** is a diagram illustrating a method of selecting one of a plurality of target devices according to an embodiment.

Referring to FIG. **11**, devices **201** through **204** that are controllable by the remote control device **100** based on the operations described above with reference to FIGS. **1** through **6** may be disposed adjacent to each other in a space.

An IR transmitter **141** included in the remote control device **100** may transmit, as a device selecting signal, an IR signal with straightness based on a direction in which the remote control device **100** faces, and the transmitted IR signal may have a predetermined angle of beam spread θ .

When target devices are located adjacent to each other within the angle of beam spread θ of the IR signal, at least two devices may receive the device selecting signal, based on the angle of beam spread θ .

For example, in FIG. **11**, a TV **201** and a desk lamp **204** may receive the device selecting signal from the remote control device **100**.

In this example, each of the TV **201** and the desk lamp **204** may transmit a response signal in response to the device

12

selecting signal. Accordingly, the desk lamp **204** together with the TV **201** a user desires to select may be selected.

In each of the TV **201** and the desk lamp **204** that receive the device selecting signal, an indicator including a light emitting element, for example, an LED may flicker during a predetermined period of time and accordingly, the user may recognize that a plurality of devices are selected.

Thus, the user may need to perform an additional operation of selecting a device that the user desires to control from among the selected devices.

When a plurality of target devices are located adjacent to each other, a specific device that the user desires to control may be easily selected based on at least one of a key input and voice of the user input to the remote control device **100**.

As described above with reference to FIG. **11**, when a plurality of devices receive an IR signal, the remote control device **100** may receive a response signal from each of the devices using an RF communication scheme. The received response signal may include identification information, control program information, and the like of each of the devices.

The remote control device **100** may transmit the received control program information to the voice recognition server **400** via the communication unit **140**, using a network, for example, a wireless Internet, and the like. The voice recognition server **400** may interpret a user command based on the received control program information.

Accordingly, when the remote control device **100** receives a response signal including control program information and information on a target device, based on an IR signal, and when a plurality of target devices are selected, the user may select a final target device through voice recognition or key input.

Hereinafter, an example in which the remote control device **100** is a portable terminal will be described, however, there is no limitation thereto. Embodiments of the present invention may be applicable to various devices capable of recognizing a user's voice by accessing the voice recognition server **400** and executing a user command.

FIGS. **12** through **15** each illustrate a UI screen of a voice recognition program, to describe a method of selecting a specific target device using voice recognition and controlling the specific target device according to a first embodiment.

Referring to FIG. **12**, when a voice recognition mode is executed in the remote control device **100**, the remote control device **100** may search for controllable devices by transmitting an IR signal using the same method as described above with reference to FIGS. **1** through **7**, while waiting for a voice input of a user using a microphone (not shown).

A user may request a desired function using the remote control device **100** in a voice, or may place the remote control device **100** in a direction that the user desires to control the remote control device **100**.

For example, when the user places the remote control device **100** to face the TV **201**, as shown in FIG. **7**, the remote control device **100** may receive a response signal including device identification information and control program information from each of the TV **201** and the desk lamp **204**, based on the angle of beam spread θ of the IR signal.

In this example, the remote control device **100** may recognize that a plurality of devices, that is, the TV **201** and the desk lamp **204** are selected, based on the received response signal.

13

Current controllability of the selected TV **201** and the selected desk lamp **204** may be displayed on a screen **121** of the remote control device **100**, in response to the IR signal, as shown in FIG. **13**.

The remote control device **100** may transfer the device identification information and the control program information received from each of the TV **201** and the desk lamp **204** to a voice recognition server **400** via the communication unit **140**, and may allow a voice control command input by the user to be interpreted by the voice recognition server **400**.

Referring to FIG. **14**, the user may finally select one of controllable devices, for example, the desk lamp **204**, as a device to be controlled.

Referring to FIG. **15**, the remote control device **100** may display a control menu corresponding to the selected device on the screen **121**.

For example, the user may select an 'OFF' button **126** displayed on the screen **121**, to turn off the desk lamp **204** that is current being in an 'ON' state, as shown in FIG. **11**.

In this example, the user may provide a voice 'OFF' to select the 'OFF' button **126**. Additionally, the voice of the user may be interpreted based on control program information on a corresponding device that is received in advance in the voice recognition server **400**.

The remote control device **100** may be used as the voice recognition server **400** to receive a result of voice recognition of the interpreted control command.

The remote control device **100** may transmit a control command corresponding to the selected target device, that is, the desk lamp **204**, based on the interpreted control command.

A result obtained by executing the transmitted control command may be displayed on the screen **121** of the remote control device **100**.

FIG. **16** is a diagram illustrating another example of a method of selecting a specific target device using voice recognition and controlling the specific target device according to an embodiment.

Referring to FIG. **16**, a target device may be selected by a user, while a control command corresponding to the selected target device is executed.

For example, when the TV **201** and the desk lamp **204** are found as controllable devices when the remote control device **100** transmits an IR signal, the user may provide a voice input 'Turn on a TV,' to select the TV **201** as a target device and simultaneously to request a command to turn 'ON' the TV **201**.

Text on the screen **121** as shown in FIGS. **12** through **16** may be output in a voice through a speaker of the remote control device **100**.

Additionally, the remote control device **100** may transmit an IR signal and may select one of a plurality of target devices as described above with reference to FIGS. **11** through **16**, however, there is no limitation thereto. Accordingly, various signals with straightness other than the IR signal may be used to select a target device, and the above control method may also be applicable to the various signals.

The methods according to the above-described embodiments of the present invention may be written as computer programs, and may be recorded in a non-transitory computer readable recording medium. Examples of the non-transitory computer readable recording medium may include a ROM,

14

a RAM, CD-ROMs, magnetic tapes, floppy disks, optical data storage devices, and carrier waves, such as data transmission through the Internet.

The non-transitory computer readable recording medium may also be distributed over network coupled computer systems so that the computer readable code is stored and executed in a distributed fashion. Also, functional programs, codes, and code segments for accomplishing the present invention may be easily construed by programmers skilled in the art to which the present invention pertains.

Although a few embodiments of the present invention have been shown and described, the present invention is not limited to the described embodiments. Instead, it would be appreciated by those skilled in the art that changes may be made to these embodiments without departing from the principles and spirit of the invention, the scope of which is defined by the claims and their equivalents.

The invention claimed is:

1. A remote control method, comprising:

transmitting a device selecting signal;

receiving a response signal from a target device that is to be controlled and that receives the device selecting signal;

identifying the target device based on the response signal;

changing at least one of an angle of beam spread and a direction of the device selecting signal, when a plurality of target devices to be controlled are identified; and generating a remote control signal based on device control information corresponding to the identified target device, and transmitting the remote control signal to the target device,

wherein the step of changing at least one of an angle of beam spread and a direction of the device selecting signal comprises:

reducing the angle of beam spread of the device selecting signal at a predetermined interval;

requesting a device that receives the device selecting signal to transmit the response signal; and

reducing the angle of beam spread of the device selecting signal until one of the plurality of target devices is selected.

2. A remote control method, comprising:

receiving at least one of a key input and a voice recognition of a user;

transmitting control program information of each of a plurality of target devices to a voice recognition server via a communication unit by using a network;

interpreting a user command based on the received control program information by the voice recognition server;

transmitting a device selecting signal in response to the interpreted user command;

receiving a response signal from a target device that is to be controlled and that receives the device selecting signal;

identifying the target device based on the response signal; selecting one of a plurality of target devices to be controlled by recognizing a user's voice, when the plurality of target devices are identified; and

generating a remote control signal based on device control information corresponding to the identified target device, and transmitting the remote control signal to the target device.
